

The coordination layer for agentic engineering teams

An introduction to **Orkestrate**

AI increased team velocity.
It also increased collisions.

The agent stack is fragmenting fast.
Teams now run multiple tools in parallel.

Orkestrate

One codebase. Many agents. Zero collisions. The ultimate
coordination layer for AI coding tools.

[Get Started →](#)

The Coordination Loop

1. Read shared state

See what every other agent is doing now.

2. Declare intent + file footprint

Claim your objective and the paths you'll touch.

3. Execute

Work in parallel with clear boundaries.

4. Publish updates

Write back progress so the next agent has context.

How Orkestrate coordinates parallel agents

Orkestrate enforces one workflow for every agent:

read shared state, declare intent + file footprint, execute, publish updates.

This prevents collisions because agents see claimed paths before starting, so overlapping work is avoided by default.

It enables parallel speed because everyone stays synchronized in real time, letting multiple agents work at once without stepping on each other.

Why now?

Agent count is scaling faster than team
coordination

Orkestrate

Land with builders, expand to engineering orgs

We start with AI-native product teams running 3–10 agents per repo, where coordination pain appears immediately.

Once teams rely on shared state and live visibility, we expand into org-level governance and enterprise controls.

Monetization aligned with coordination-critical usage

Free drives onboarding through MCP integrations, while Team monetizes through seats and active agent concurrency.

Enterprise adds policy controls, audit exports, SSO/SCIM, and reliability commitments, so revenue scales with operational dependency rather than casual prompt usage.

Agentic Engineering is the future where the
bottleneck is coordination.
We're here to solve it

Thank you — Team Orkestrate
